

White LED Charge Pump With LDO

FEATURES

- Powers Up to 5 LEDs for BackLight & One Adjustable LDO Supply.
- Up to 25mA/LED Drive for Backlight
- Up to 100mA Total Drive for LDO
- Single-Wire 8-Step Brightness/Voltage Control
- Over temperature Over Voltage, Output Short Protection
- Soft Start with Low Input Ripple and EMI
- Maximized Efficiency
- 2.7V to 5.5V Supply Voltage Range
- 3mmx3mm 16-Pin QFN Package

DESCRIPTION

The BL250 is a low noise charge pump LED driver with regulated constant current sink for uniform intensity. It is designed to drive five LEDs (LED1-LED5) at up to 25mA per LED for backlighting application, and one adjustable LDO voltage supply (VLDO) for general-purpose application, which can supply up to 100mA of DC power. The BL250 requires only four small ceramic capacitors and one current set resistor for a complete LED power supply or add one capacitor and one resistor for LDO application.

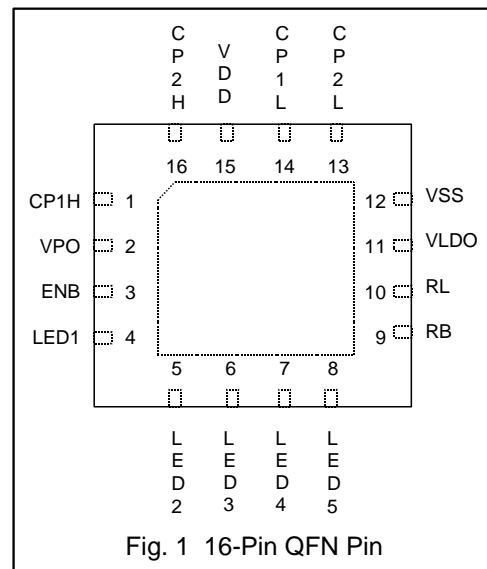

Built-in soft-start circuitry prevents excessive inrush current during start-ups. The 1MHz fixed-frequency switching allows for tiny external components, and the regulation scheme is optimized to ensure low EMI and low input ripple. The Backlight full-scale current setting is set by an external resistor on RB pin. The LDO supply full-scale voltage setting is

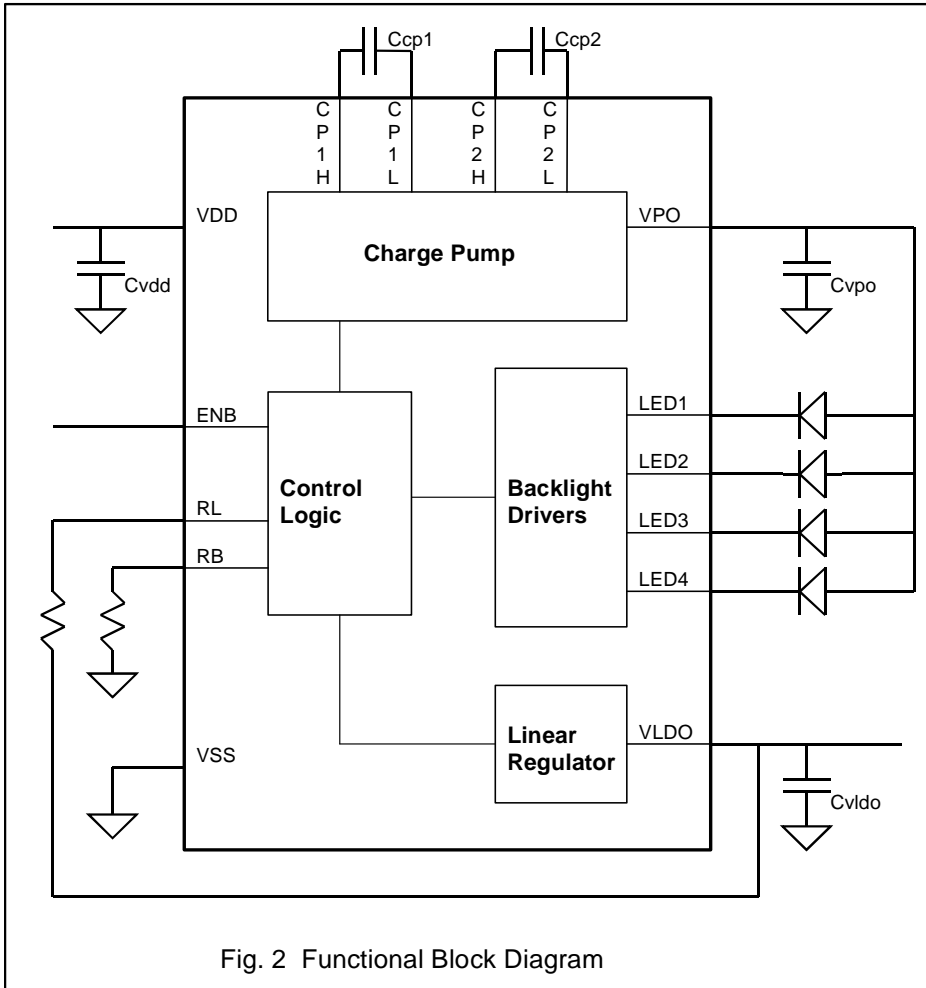

done through a resistor between RL and VLDO pins.

Shutdown mode and current output levels for the LED drivers are selected via logic input ENB pin. ENB is toggled to adjust the LED currents via internal counters and DACs. The part is shut down when ENB is Low for >10 μ s.

The charge pump optimizes efficiency based on the voltage across the LED current sources. The BL250 is available in a 3mm x 3mm 16-lead QFN package.

PIN ASSIGNMENT

PIN DESCRIPTION

PIN	SYMBOL	DESCRIPTION
1, 14, 16, 13	CP1H, CP1L, CP2H, CP2L	Pump Capacitor Pins, A 1 to 2.2 μ F ceramic capacitor should be connected from CP1H to CP1L and CP2H to CP2L.
2	VPO	Pump Output, Used to Power All LEDs. This pin is enabled or disabled using the ENB input. A 1 to 2.2 μ F ceramic capacitor should be connected to ground
3	ENB	Inputs. The ENB pin is used to program the LED output currents. The counter is decremented on the rising edge of the strobe signal. The counter data is transferred to the driver bias circuit after a 10 μ s delay. If ENB input is held Low or leaved open for longer than 10 μ s the part will go into shutdown.
4, 5, 6, 7, 8	LED1, LED2, LED3, LED4, LED5	Outputs. LED1 to LED5 are the Backlight current source outputs. The LEDs are connected between VPO (anodes) and LED1-5 (cathodes). The current to each LED output is programmed via the ENB input, and the full-scale setting resistor connected between RB and VSS.
9	RB	LED Full-Scale Current Resistor Pin. Resistor connected between this pin

Preliminary specification

		and VSS is used to set the full-scale current for LED1-LED5 drivers.
10	RL	Analog Input, Resistor connected between RL and VLDO pins sets the voltage on VLDO output.
11	VLDO	Output. VLDO is the low drop off supply output. The voltage to the VLDO output is set by the resistors between VSET to VLDO and VSET to VSS. The VLDO voltage range is from 1.2V to 5V.
12	VSS	Ground. This pin should be connected to a low impedance ground plane.
15	VDD	Supply voltage. This pin should be bypassed with a 2.2 μ F, or greater low ESR ceramic capacitor.
17	Exposed Pad	This pad should be connected directly to a low impedance ground plane for optimal thermal and electrical performance.

FUNCTIONAL DESCRIPTION

1) Power Management

The BL250 uses a switched capacitor charge pump to boost VPO output to as much as 2 times the input voltage up to 7V. A two phase non-overlapping clock activates the charge pump switches. The pump capacitors are charged on alternate clock phases from VDD to minimize input current ripple and VPO output voltage ripple. This sequence of charging and discharging the pump capacitors continues at a constant frequency of 1MHz .

2) LED Brightness/Dimming Control

The brightness of the LEDs may be controlled by varying the current flow through the LED. The LED1-LED5 currents are delivered by five programmable current sources. Eight current settings (0mA to 24mA, $R_B = 8.0k$) are available by strobing the ENB pin. Each rising edge of the strobe signal decrements a 3-bit down counter which controls an exponential DAC. The output current then changes to the programmed value at about 10uS after the strobe signal has stopped. The counter will wrap around when strobing passes 0. The width of the strobe signals are limited to within 200nS for both High and Low pulses. The programming requirements are as shown in Fig. 3.

The full-scale output current is calculated as follows:

$$LED1-LED5 = (0.6V/R_B) \cdot 320$$

Table 1 below shows the normalized correspondent counter values.

Count	LED1-LED5
7	24mA
6	12mA
5	6mA
4	3mA
3	1.5mA
2	0.75mA
1	0.375mA
0	0mA

Table 1 Counter Values (normalized per $R_B=8.0k$)

3) The LDO output voltage is adjustable through a resistor connected between RL and VLDO pins. The available voltage on VLDO is from 1.2V to 5V. The full-scale output voltage is calculated as follows:

$$V_{ldo} = R_L \cdot 20E-6 + 0.6$$

4) Soft-Start

The BL250 employs a soft-start feature on its charge pump to prevent excessive inrush current and supply droop when the part is

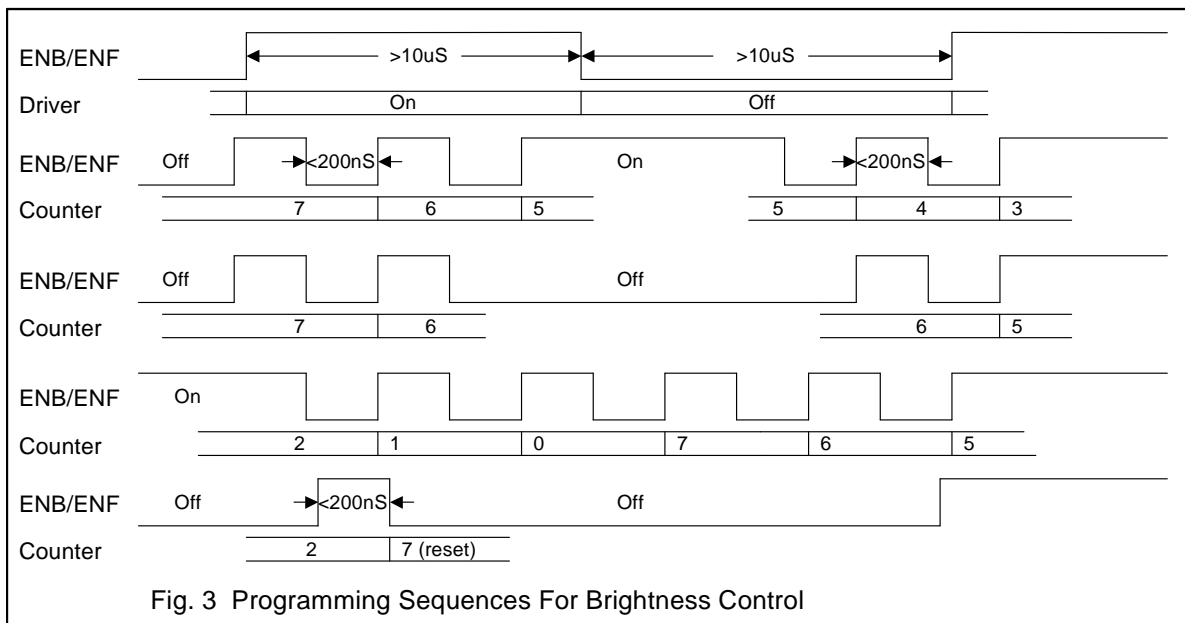

Fig. 3 Programming Sequences For Brightness Control

Preliminary specification

enabled. The current available to the VPO pin is increased gradually. This allows VDD to slowly charge the VPO output capacitor to prevent large charging currents.

5) Shutdown Current

In shutdown mode all the circuitry is turned off and the BL250 draws theoretically zero amount of current from the VDD supply. The BL250 enters shutdown mode when ENB pin is Low for >10µs. ENB input has 130k internal pull down resistor which will set the device in shutdown mode when this pin is in a high impedance state.

5) Thermal Protection

The BL250 has built-in over temperature protection. At internal junction temperatures of around 120°C a thermal shutdown will occur. This will disable all of the current sources and charge pumps as if it is in

shutdown mode until the die has cooled by about 50°C. This thermal cycling will continue until the fault has been corrected.

6) Short Circuit Protection

When VPO or VLDO pin experiences an output loading of less than 10Ω and without any diode characteristics during start up, the device will consider this as a short circuit condition and limit the VPO plus LDO current to within 30mA. This will continue until the fault is removed or the device is put in shutdown mode.

7) Unused LED Output

The unused driver pins should be left unconnected. The device will automatically detect the unused outputs during start up and have them disabled.

Electrical Characteristics

ABSOLUTE MAXIMUM RATINGS

PARAMETER	MAX	UNITS	NOTES
Supply Voltage	8	V	Vdd pin

APPLICATIONS INFORMATION

1) VDD, VPO Capacitor Selection

The style and value of the capacitors used with the BL250 determine several important parameters such as regulator control loop stability, output ripple, charge pump strength and minimum start-up time.

To reduce noise and ripple, it is recommended that low equivalent series resistance (ESR) ceramic capacitors are used for both VDD and VPO decoupling capacitors. Tantalum and aluminum capacitors are not recommended due to high ESR. The excessive output capacitor $ESR > 100m\Omega$ will tend to degrade the loop stability. Multilayer ceramic chip capacitors typically have exceptional ESR performance and when combined with a tight board layout will result in very good stability. The value of VDD decoupling capacitor controls the amount of ripple present at the VDD input. The BL250's input current will be relatively constant while the charge pump is either in the input charging phase or the output

charging phase but will drop to zero during the clock non-overlap times. Since the non-overlap time is small (<40ns), these missing "notches" will result in only a small perturbation on the input power supply line. Note that a higher ESR capacitor such as tantalum will have higher input noise due to the higher ESR. Therefore, ceramic capacitors are recommended for low ESR. Input noise can be further reduced by powering the BL250 through a very small series inductor. A 10nH inductor will reject the fast current notches, thereby presenting a nearly constant current load to the input power supply. For economy, the 10nH inductor can be fabricated on the PC board with about 1cm (0.4") of PC board trace.

2) Pump Capacitor Selection

Warning: Polarized capacitors such as tantalum or aluminum should never be used for the pump capacitors since their voltage can reverse upon start-up of the BL250. Ceramic capacitors should always be used for the pump capacitors.

Preliminary specification

The pump capacitors control the strength of the charge pump. In order to achieve the rated output current it is necessary to have at least 1 μ F of capacitance for each of the pump capacitors. Capacitors of different materials lose their capacitance with higher temperature and voltage at different rates. For example, a ceramic capacitor made of X7R material will retain most of its capacitance from -40°C to 85°C whereas a Z5U or Y5V style capacitor will lose considerable capacitance over that range. Capacitors may also have a very poor voltage coefficient causing them to lose 60% or more of their capacitance when the rated voltage is applied. Therefore, when comparing different capacitors, it is often more appropriate to compare the amount of achievable capacitance for a given case size rather than comparing the specified capacitance value. For example, over rated voltage and temperature conditions, a 1 μ F, 10V, Y5V ceramic capacitor in a 0603 case may not provide any more capacitance than a 0.22 μ F, 10V, X7R available in the same case. The capacitor manufacturer's data sheet should be consulted to determine what value of capacitor is needed to ensure minimum capacitances at all temperatures and voltages.

3) Layout Considerations and Noise

Due to the high transient currents produced by the BL250, careful board layout is necessary. A true ground plane and short connections to all capacitors will improve performance and ensure proper regulation under all conditions.

The pump capacitor pins CP1H, CP2H, CP1L and CP2L will have high edge rate waveforms. The large dv/dt on these pins can couple energy capacitively to adjacent PCB runs. Magnetic fields can also be generated if the pump capacitors are not close to the BL250 (i.e., the loop area is large). To decouple capacitive energy transfer, a Faraday shield may be used. This is a grounded PCB trace between the sensitive node and the BL250 pins. For a high quality AC ground, it should be returned to a solid ground plane that extends all the way to the BL250.

The following guidelines should be followed when designing a PCB layout for the BL250:

- The exposed pad should be soldered to a large copper plane that is connected to a solid, low impedance ground plane using plated through-hole vias for proper heat sinking and noise protection.
- Input and output capacitors must be placed close to the part.
- The pump capacitors must be placed close to the part. The traces from the pins to the capacitor pad should be as wide as possible.
- VDD, VPO traces must be wide to minimize inductance and handle high currents.
- LED pads must be large and connected to other layers of metal to ensure proper heat sinking.
- RB and RL pins are sensitive to noise and capacitance. The resistors should be placed near the part with minimum line width.

4) Thermal Management

For higher input voltages and maximum output current, there can be substantial power dissipation in the BL250. If the junction temperature increases above approximately 120°C the thermal shut down circuitry will automatically deactivate the output current sources and charge pump. To reduce maximum junction temperature, a good thermal connection to the PC board is recommended. Connecting the Exposed Pad to a ground plane and maintaining a solid ground plane under the device will reduce the thermal resistance of the package and PC board considerably.

5) Power Efficiency

To calculate the power efficiency (Epo) of a white LED driver chip, the LED power should be compared to the input power. The difference between these two values represents lost power whether it is in the charge pump or the current sources. Stated mathematically, the power efficiency is given by:

$$Epo = P_{out} / P_{in}$$

The efficiency of the BL107 depends upon the mode in which it is operating. Recall that the BL107 operates as a pass switch, connecting VDD to VPO, until dropout is detected at the LED pins. This feature provides the optimum efficiency available for

a given input voltage and LED forward voltage.

When it is operating as a switch, the typical efficiency is approximated by:

$$E_{po} = P_{out}/P_{in} = (I_{po} \times V_{po}) / (I_{dd} \times V_{dd})$$

since the input current will be very close to the sum of the LED currents. At moderate to high output power, the quiescent current is negligible and the expression above is valid. When V_{dd} has dropped to a level which can not sustain the set LED current, BL107 will enable the charge pump in 2x mode.

In 2x boost mode, the efficiency is similar to that of a linear regulator with an effective input voltage of 2 times the actual input voltage. This is because the input current for a 2x charge pump is approximately 2 times the load current. Therefore a typical 2x charge pump without any optimization, the power efficiency would be given by:

$$E_{po} = P_{out}/P_{in} = (I_{po} \times V_{po}) / (2I_{po} \times V_{dd}) \\ = V_{po} / (2V_{dd})$$
